Step gauges for checking the accuracy of co-ordinate measuring machines

In industrial metrology, actual physical bodies of known length which can be contacted by mechanical sensors have an important part to play as reference standards when measuring geometrical parameters.

They have become particularly important for assessing the accuracy of two and three-axis co-ordinate measuring machines which employ mechanical sensors. Checking the length measurements uncertainty has proved to be a highly informative and economical method for the acceptance testing and ongoing monitoring of co-ordinate measuring machines. In this case the step gauge can be used in an enormous variety of ways, giving, for example, the advantages of uni-directional and bi-directional targetting and of measurements from all the gauge faces along a line of measurement in succession while needing only a short time for preparation and measurement. Local errors can be detected in the co-ordinate measuring machine and characteristics can be derived for individual co-ordinate axes of the machine.

With the aid of the length measurement uncertainty, the manufacturer or user can specify and check the accuracy of a co-ordinate measuring machine to establish its suitability for length measurement. This fundamental task in metrology is of particular importance due to the fact that in practice the majority of measuring requirements are for the measurement of lengths.

"Length measurement uncertainty" is defined by VDI/VDE guideline 2617, part 2.1 as the uncertainty with which a co-ordinate measuring machine allows the precisely known distance between two points on two mutually parallel gauge faces situated in succession along a line of measurement to be remeasured. Fig. 1 shows a measurement of this kind being made, taking as an example an individual parallel gauge block with an outside length L_e which is arranged obliquely in three dimensions and whose length is remeasured by successive contacts with the block with the probe head in positions I and II.

On the step gauge, spacings of different kinds for making test measurement are all available simultaneously, as follows:

- Outside dimension L_e e.g. with the probe head in positions I and II (Fig. 2)
- Inside dimension L_i e.g. with probe head in positions III and IV (Fig. 3)
- Rear-face to rear-face dimension L_s e.g. with probe head in positions III and V (Fig. 3)
- Front-face to front-face dimension L_s e.g. with probe head in positions VI and IV (Fig. 3)
- Positional length (L_p of a gauge face from the datum gauge face, e.g. with probe head in positions VI and 0 (Fig. 3)

The illustrations show only one of many options available for each type and size of spacing. In magnitude, the differences between the length value L_a indicated by the co-ordinate measuring machine or printed or displayed by its output processor and the true value L_r of the measurement uncertainty U .

What this means is that L_a can be both larger and smaller than L_r .

The value of the length measurement uncertainty is generally given in the form of a length-dependent formula: $U = A + K \cdot L \leq B$.

A distinction should be made between the figure U_1 specified for one-dimensional test measurements along a co-ordinate axis (with terms A_1, K_1, B_1), the figure U_2 for two-dimensional test measurements made diagonally in a co-ordinate plane (with terms A_2, K_2, B_2) and the figure U_3 for three-dimensional test measurements made diagonally in the three-dimensional space defined by the co-ordinates (with terms A_3, K_3, B_3).

Fig. 1:
Individual gauge block arranged obliquely in three dimensions on the table of a co-ordinate measuring machine, showing an outside dimension L_e being measured.

Graphic representation and analysis

Length measurement uncertainty plot

For the purposes of graphic analysis, the differences $\Delta L = L_a - L_r$ which are found are plotted, with the correct signs, for the individual measured lengths and runs in a length measurement uncertainty grid (Fig. 4). The top and bottom boundary lines produce a funnel-shaped outline with the neck of the funnel measuring $2A$ (A = figure specified by manufacturer for length measurement uncertainty irrespective of length). 95 % of all the test measurements must lie within or on the boundaries. A quantitative analysis is made simply by counting the number of measurements which lie outside the boundary lines.

Gauge face position plot

With the step gauge it is also possible to test the positions L_p of the gauge faces as distances from the datum face. If the relevant length errors ΔL_p given by position measurement in line with VDI guideline 2617 Part 3 are entered in a plot, then it is possible to see both the position of the test length and also the sequence if for example the measurement points in a run are connected by straight lines. With a set of individual gauge blocks this is not possible because they do not have any true common reference point and are not situated on a measurement line.

For analysis use is made of a gauge face position grid (Fig. 5) (similar to the length measurement uncertainty grid). The outline is symmetrical and similar in shape to a butterfly with a width across the waist of $1A$. The parameters in this case correspond to the appropriate figures A_1 , K_1 , B_1 and so on. As this grid is moved along the measured length L , at least 95 % of all the measurements must always lie within or on the boundary lines, meaning that all the measurement points must do so consistently whatever the position of the waist. This ensures that any pairing of two gauge faces (even from different runs) in the form of outside, inside or face-to-face dimensions will also lie inside the funnel of the length measurement uncertainty grid. Thus, the grid forms a combined graphic expression of both the equations given above for all points of measurement.

Comparison between the test standards gauge blocks and step gauges

Apart from the step gauge, the reference standards which lengths are known with the greatest accuracy are parallel gauge blocks. These however are relatively flexible and have to be mounted at the AIRY points (symmetrical spacing $a = 0.57735 \cdot L$) so that they are free of bending moments if this parallelism of the gauge faces is to be maintained. The gauge blocks for the individual test lengths can be individually placed one behind the other for shorter lengths and next to one another for longer lengths. However, when this is done there is no way of obtaining the different gauge points along a line of measurement which are desirable for measurement purposes.

Special features and advantages of the KOBA-step

The step gauge is of castellated configuration and in it a large number of forward and backward facing gauge faces are lined up along a single line of measurement. This line of measurement is the same for measurements between any faces and the position of the workpiece, that is to say the orientation of the carrying body, only has to be determined once to find this line. There are numerous possible combinations in various positions along the measurement line, that actual number of different interface dimensions for a step gauge with 26 castellations (= KOBA-step with a nominal size of 1020 mm) being 1326.

The special feature of the KOBA-step step gauge is the fact that the actual gauge points are situated on the neutral fibre of the carrying body and this means that there are no first-order changes in length if the state of bending changes.

The configuration of the carrying body and the fact that the line of measurement is situated on the neutral fibre prevents any increase in the distance between the gauge faces at the points where the carrying body is supported and prevents them from moving closer together at intervening points. In the KOBA-step step gauge, which is neutral in bending, cylindrical gauge blocks are fixed in position individually in an internal longitudinal groove formed in a rugged steel carrying body of square section (55 x 55 mm). The axis of the gauge blocks is situated on the fibre of the carrying body which is neutral in bending and they form a series of castellations. The arrangement which has been adopted provides excellent protection for the gauge faces. The strength of the carrying body and the fact that the lengths do not vary if there are changes in the bending to which it is subject mean that the KOBA-step gauge can be mounted in a wide variety of fashions, e.g. cantilevered with so-called zero position support or with support at the Besselpoints.

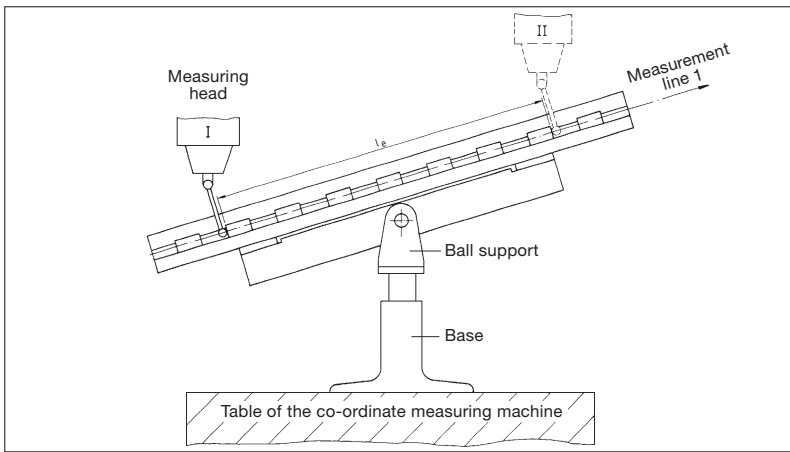

Fig. 2:

$$U = A + K \cdot L \leq B$$

with the possibility of different plots for U_1 , U_2 , U_3 which represent one, two and three-dimensional length measurement uncertainties

Accessories

The range of accessories available which are needed for use with the step gauge, such as swivel support, and base allows the gauge body to be mounted on the co-ordinate measuring machine in such a way as to be free of torsion. A support of this kind produces a particularly stable connection between the step gauge and the table of the co-ordinate measuring machine (Fig. 7, 9 and 10).

The combination of the step gauge and its accessories produces a complete system for making an overall check on the co-ordinate measuring machine.

One particularly important point is that the procedure of checking the co-ordinate measuring machine can be carried out fully automatically under computer control.

Traceability

Since the acceptance or refusal of a co-ordinate measuring machine may depend on the outcome of the length measurement uncertainty test, it is advisable always to use officially calibrated testing equipment in order to avoid unpleasant surprises and wrong interpretations. The KOBA-step step gauge is available with both DKD calibration-certificate (German Calibration Service-DKD) and Works Calibration.

Below are the length measurement uncertainties which can currently be achieved with the step gauge up to 1020 mm:

DKD: $U = 0,10 \mu\text{m} + 0,5 \cdot 10^{-6} \cdot L \geq 0,12 \mu\text{m}$
Works Calibration: $U = 0,3 \mu\text{m} + 0,8 \cdot 10^{-6} \cdot L$ (length)

Recalibration

As is normal with all measurement standards, the KOBA-step step gauge should be recalibrated after a certain period. We recommend the following recalibration intervals:

First recalibration after one to two years and each successive recalibration after two to three years.

Alignment of the KOBA-step

To define the position and orientation of the KOBA-step resp. the measuring line within the measuring volume, we recommend proceeding as follows:

As the carrying body with the fixed cylindrical gauge blocks has been designed symmetrically to both sides, one of the external side surface and the upper external surface at the end of the large U-groove can be used for the alignment.

Any points which are as large as possible can be sensed at the side surface and at the upper external surface likewise. Both planes so defined are squared off mathematically. A parallel line 27,5 mm to the side surface and 30 mm to the upper surface is the measurement line situated on the neutral fibre.

It is also possible to use both ends of the 7 x 10 mm interior groove for the alignment and proceed in a similar way as mentioned before. The distance from the wall of the groove and the floor of the groove to the line of measurement is 5 mm in both directions.

Cross drills for easy contacting of the measuring faces.

Fig. 7:
 KOBA-step aligned horizontally along the X-Y plane diagonal, approx. 500 mm above the table, stylus probe vertical.
 Accessory: Base and swivel support.

Fig. 8:
 KOBA-step aligned along the X-axis (lying flat on the table with no accessories used), stylus probe vertical.

Practical Use

Practical experience in using the KOBA-step step gauge for checking the accuracy of co-ordinate measuring machines and assessing and interpreting the results has demonstrated the usefulness and potentially high information yield of the “length measurement uncertainty” method. The advantage lies in the fact that the measurement is carried out at precision gauge faces using the normal gauging procedure and in the main, the machine manufacturer’s standard processing software. Since the unidirectional and bi-directional gauging of inside and outside dimensions, dimensions between similarly orientated surfaces, and successive dimensions from a given point occur even in the routine measurement of work pieces and since the measurements which have been obtained can be correlated with one another as desired even after the event, it is good idea to make full use of the opportunities offered by the step gauge. What is more, a series of measurements at all the gauge faces in succession provides a large amount of interrelated information and requires only a short time for measurement.

Since the length measurement uncertainty characteristic very much depends on the geometry of the co-ordinate measuring machine, the lines along which measurements are made should be as follows:

- 3 to 4 measurement lines which are diagonal in three dimensions (i.e. along the diagonals of an inscribed cube – at a gradient of approximately 35° – or along the diagonals of the cuboid representing the measured space).
- 2 diagonal lines of measurement in each co-ordinate plane (i.e. along the diagonals of a square – at a gradient of 45° – or the diagonals of a rectangle).
- At least one line of measurement parallel to each co-ordinate axis.

At least 18 suitable lines of measurement have to be selected in order to arrive at a complete definition of the 18 geometrical cuboid characteristics of the entire measurement volume.

It has to be stressed in particular that reliable measurement results for the complex system cannot be achieved unless the stylus probes are included. Checking of the co-ordinate measuring machine without mechanically contacting, i.e.: without using a probe, will therefore not result in an comprehensive statement about the accuracy of the measuring machine.

Fig. 13: KOBA-step with swivel support and base, illustrated at various angular inclinations (stylus probe not shown).

Fig. 14: KOBA-step, equipped with swivel support base Size 1 for accommodating 1020 mm length step-gauge (stylus probe not shown).

**Another KOBA-step application area:
Conducting formal acceptance procedures and monitoring the precisions of machine tools and robotic dimensional-gauging systems**

The step gauge KOBA-step may be used for checking the positioning accuracies of machine tools and articulated-arm robotic dimensional-gauging systems, an application area where they offer the same elegant approach and speed as in checking co-ordinate measuring machines. The accessory items required here are those described above, a swivel support and base.

Regular use of the KOBA-step for monitoring dimensional-gauging precisions of machine tools is essential to total quality assurance. Total quality assurance demands more than mere precision dimensional gauging of finished work and components; regularly monitoring the dimensional-gauging precisions of the machine tools employed in their fabrication is indispensable. Finished products must be machined to within prescribed dimensional tolerances if they are to pass final acceptance checks. Regular monitoring of machine tool dimensional-gauging precisions provides valuable information on the degrees to which work/component dimensional tolerances are being maintained in machining operations.

Fig. 15: KOBA-step installed on a swivel support and base, shown here spanning the major diagonal of the workspace of a vertical milling machine equipped with a dimensional-gauging head.

Fig. 17: KOBA-step, shown here aligned vertically for checking the Z-axis of a machine tool equipped with a dimensional-gauging head.

Fig. 18: KOBA-step, shown here installed on a flexible machining center for verifying its positioning accuracy (the center's dimensional-gauging head is integrated into its tool chuck).

Standard nominal lengths

nominal length mm	number of gauge faces	overall length	weight kg
420	22	480	6.5
620	32	680	9.5
1020	52	1080	15.0
1540	78	1600	23.0
2020	102	2080	30.0

The nominal length of a step gauge is the distance from the first gauge face to the last gauge face. Special sizes on enquiry, at present available with length up to 2500 mm.

Following characteristics identical for all lengths listed:

Cross-section of holder:
55 x 55 mm

Cross-section of cylindrical gauge blocks:
10 mm diameter

Length of castellations:
20 mm

Space between castellations:
20 mm

Ideal

Standard design with gauge faces of ceramic

Advantages:

- corrosion resistant
- Stable in size
- less cleaning
- coefficient of expansion similar to steel
- wear resistance similar to carbide

Existing step gauges with cylindrical steel gauge blocks can be exchanged against ceramic. However, a re-calibration is necessary then.

KOBA-step *mini*

System for the calibration and monitoring of multi-sensor measuring instruments and coordinate measuring instruments of small measuring volume

Special features

The KOBA-step *mini* is a step gauge of the "KOBA-step" type but with harmoniously reduced cross-section and resized gauge block distance according to the measuring length and measuring task. The methodical advantages such as embedding of the cylindrical gauge blocks in the neutral fibre of the carrying body and the good access from three sides have been maintained. The length and distances of the gauge blocks were reduced to 10 mm

according to the total lengths which allow to recognize local errors of the measuring instrument.

The cylindrical gauge blocks are made of zirconia ceramic thus free of corrosion and wear.

The system is completed by the swivel support included in the delivery and by which the KOBA-step *mini* can be mounted horizontally, vertically or in the volume.

The traceability to the National Length Standard is guaranteed by works calibration or through DKD or PTB.

KOBA-step *mini* on the measuring instrument positioned in the volume

Ceramic gauge blocks on the neutral fibre

Scope of supply:

KOBA-step *mini* with probing elements in zirconia ceramic, base and swivel mechanism for positioning from 0° to 90° (horizontally or vertically) as well as aluminium storage case

Standard lengths

Nominal length mm	Number of castellations/ probing faces	Division mm	Overall length mm
210	11/22	10	220
310	16/32	10	320

A brief review of the **KOBA-step** step gauge

For the first time, this gauge block combines the advantages which step gauges offer the user with the ability to meet the stringent metrological demands which a precision measurement standard has to meet:

- ▶ Available with various standard nominal lengths (210, 310, 420, 620, 1020, 1540 and 2020 mm) with even steps (castellation/gap = 10/10 mm, from 420 mm = 20/20 mm), also with different standard lengths and uneven steps (however, castellation = 10 mm, from 420 mm = 20 mm) for an optimal adjustment to the measurement task.
- ▶ Stainless finish guaranteed by special surface treatment.
- ▶ The gauge faces used are the specially machined end faces of cylindrical gauge blocks which are inset solidly into position in a groove by a special process.
- ▶ Gauge faces lapped for correct sensing.
- ▶ Carrying body specially aged for longterm stability.
- ▶ Solid connection between the cylindrical gauge blocks with gauge faces and the carrying body.
- ▶ Cylindrical gauge blocks deeply inset to protect them against damage, length 20 mm.
- ▶ Gauge faces conically reduced to 5 mm diameter, hence easy to clean.
- ▶ The centres of the gauge faces are located on the fibre of the carrying body which is neutral in bending. As a result changes in bending stress due to different horizontal or inclined or vertical orientations have an effect on the distances between the gauge faces which is so small that it can be ignored completely.

- ▶ Because of the configuration adopted, the bending characteristics in the two principal planes are identical, and it is therefore equally possible for the gauge block to be orientated with the groove facing upwards (e.g. for vertical quills) or to one side (e.g. for horizontal quills) or downwards (e.g. for under-floor measuring machines with vertical quills operating from below). The measurements to determine the position of the carrying body in space can be carried out on the precision-machined rectangular groove.
- ▶ The longitudinal grooves in the side faces allow a wide variety of orientations and mounting methods on the table of the machine.
- ▶ The material of the carrying body determines its expansion characteristics ($\alpha = 11,5 \cdot 10^{-6}/^{\circ}\text{C}$).
- ▶ The accuracy required is of a standard not achieved hitherto and is ensured by the use of a special laser interferometer comparator which gives the precise position of each gauge face. The numerical value (Actual value according to the Calibration chart) representing the position is not generally a whole-number decimal and qualifies immediately to direct the co-ordinate measuring machine and resp. for the evaluation of the length measurement uncertainty.
- ▶ Additional reliability in everyday use because the length of each individual cylindrical gauge block is known and does not vary and must be re-measured accurately by the co-ordinate measuring machine itself with the step gauge in any position and orientation.
- ▶ Cross drills between the castellations for easy sensing of the measuring faces.
